# A MEASUREMENT OF SEMI INCLUSIVE DEEP INELASTIC SCATTERING PION ASYMMETRIES 

T. Didberidze and T. Forest<br>Department of Physics, Idaho State University, Pocatello, ID 83201, USA

December 17, 2012

#### Abstract

Semi-inclusive deep inelastic scattering (SIDIS) experiments may be used to identify the flavor of the quark that participates in the scattering process. Semi-inclusive scattering is defined as an electron scattering experiment in which the scattered electron and one hadron are detected in the final state. Experiments at Jefferson Lab have used longitudinally polarized electron beams to probe longitudinally polarized Hydrogen $\left({ }^{15} \mathrm{NH}_{3}\right)$ and Deuterium $\left({ }^{15} \mathrm{ND}_{3}\right)$ targets to investigate the quark's contribution to the properties of a nucleon. This work reports a measurement of SIDIS pion asymmetries using the CEBAF Large Acceptance Spectrometer (CLAS) at Thomas Jefferson National Laboratory. The incident electron's energy was 4.2 GeV and covered a kinematic region where the struck quark carries at least $30 \%$ of the nucleons total momentum ( $x_{B} \geq 0.3$ ). The electrons scatter mostly from valence quarks in this kinematic region allowing measurements which are less sensitive to the ocean of quark-antiquark pairs that are also inside a nucleon.

## Chapter 1

## Data Analysis

Semi-inclusive deep inelastic scattering (SIDIS) experiments using longitudinally polarized hydrogen $\left({ }^{15} \mathrm{NH}_{3}\right)$ and deuterium $\left({ }^{15} \mathrm{ND}_{3}\right)$ targets and a longitudinally polarized electron beam can be used to measure the ratio of the polarized valence quark distribution function to the unpolarized. Semiinclusive scattering identifies an electron scattering experiment in which the scattered electron and one hadron are detected in the final state. This chapter describes the techniques used to analyze the data collected during the EG1b experiment and calculate semi-inclusive asymmetries for the following reactions: $\vec{e}^{-} \vec{N} \rightarrow e^{-} \pi^{+} X$ and $\vec{e}^{-} \vec{N} \rightarrow e^{-} \pi^{-} X$ using $\mathrm{NH}_{3}$ and $\mathrm{ND}_{3}$ polarized targets respectively. The goal of this work is to measure charged pion asymmetries defined according to the incident electron helicity and the target polarization. This work focuses on a kinematic region where the struck quark carries at least $30 \%$ of the nucleons total momentum ( $x_{b}>0.3$ ). The leptons scatter mostly from valence quarks in this kinematic region allowing contributions from sea quarks to be neglected. SIDIS measurements are able to distinguish between the predictions made by the hyperfine perturbed constituent quark model ( pCQM ) and perturbative Quantum Chromodynamics (pQCD).

### 1.1 The CLAS Data Selection

The data files from the EG1b experiment chosen for this analysis are listed in Table 1.1. During the experiment, $2.2 \mathrm{GeV}, 4.2 \mathrm{GeV}$ and 5.7 GeV longitudinally polarized electron beams were used to probe the polarized $\mathrm{NH}_{3}$ and $\mathrm{ND}_{3}$ targets. This work will discuss the analysis of the 4.2 GeV electron beam data set as this energy provided the most statistics. The restrictions applied to the reconstructed events are described below.

| Run Set | Target Type | Torus Current(A) | Target Polarization | HWP |
| :---: | :---: | :---: | :---: | :---: |
| $28100-28102$ | $\mathrm{ND}_{3}$ | +2250 | -0.18 | +1 |
| $28106-28115$ | $\mathrm{ND}_{3}$ | +2250 | -0.18 | -1 |
| $28145-28158$ | $\mathrm{ND}_{3}$ | +2250 | -0.20 | +1 |
| $28166-28190$ | $\mathrm{ND}_{3}$ | +2250 | +0.30 | +1 |
| $28205-28217$ | $\mathrm{NH}_{3}$ | +2250 | +0.75 | +1 |
| $28222-28236$ | $\mathrm{NH}_{3}$ | +2250 | -0.68 | +1 |
| $28242-28256$ | $\mathrm{NH}_{3}$ | +2250 | -0.70 | -1 |
| $28260-28275$ | $\mathrm{NH}_{3}$ | +2250 | +0.69 | -1 |
| $28287-28302$ | $\mathrm{ND}_{3}$ | -2250 | +0.28 | +1 |
| $28306-28322$ | $\mathrm{ND}_{3}$ | -2250 | -0.12 | +1 |
| $28375-28399$ | $\mathrm{ND}_{3}$ | -2250 | +0.25 | -1 |
| $28407-28417$ | $\mathrm{NH}_{3}$ | -2250 | +0.73 | -1 |
| $28456-28479$ | $\mathrm{NH}_{3}$ | -2250 | -0.69 | +1 |

Table 1.1: EG1b runs analyzed for this work.

### 1.2 Particle Identification

The sections below describe the additional tests performed on the electron and a pion candidates reconstructed by the standard CLAS software package. Electrons are identified by matching the charged particle hits in the

Cherenkov counter (CC), electromagnetic calorimeter (EC), and the time of flight system (ToF). Geometrical and timing cuts are applied to improve electron identification [3]. In addition, cuts are applied on the energy deposited by the particle into the calorimeter and the number of photoelectrons produced in the Cherenkov counter. Charged pions are identified by matching the hits in the drift chamber and ToF counter, along with a Cherenkov cut requiring that the number of photons for pions be less than two.

### 1.2.1 Electron Identification

The CLAS trigger system required a particle to deposit energy in the electromagnetic calorimeter and illuminate the Cherenkov counter within a 150 ns time window (Figure 1.1). Unfortunately, this trigger suffers from a background of high energy negative pions that may be misidentified as electrons. The pion contamination of the electron sample is reduced using cuts on the energy deposited in the electromagnetic calorimeter and the momentum measured by reconstructing the particle's track in the known magnetic field. The energy deposition mechanism for the pions and electrons in the electromagnetic calorimeter is different. The total energy deposited by the electrons in the EC is proportional to their kinetic energy, whereas pions are minimum ionizing particles and the energy deposition is independent of their momentum (Figure 1.2). The pion background is further suppressed using geometrical and time matching cuts between the Cherenkov counter hit and the measured track in the drift chamber.

Fig. 1.1: Example of electron passing through the drift chambers and creating the signal in the Cherenkov counter and electromagnetic calorimeter. Electron track is highlighted by the blue line (Run number 27095, Torus Current +2250 (inbending)).

## EC CUTS

The CLAS electromagnetic calorimeter was used to reduce the misidentification of electron and negative pion candidates. The electromagnetic calorimeter contains thirteen layers of lead-scintillator sandwiches composed of $\sim 2 \mathrm{~mm}$ thick lead and 10 mm thick scintillator. Each set of thirteen layers is subdivided into five inner and eight outer layers that are named the inner and outer calorimeter respectively.

Electrons interact with the calorimeter producing electromagnetic showers that release energy into the calorimeter. The deposited energy is proportional to the momentum of the electrons. Figure 1.3 shows the correlation of

Fig. 1.2: Momentum versus ECtotal.
the inner and outer calorimeter electron candidate's energy measured by the calorimeter and divided by the particle's momentum reconstructed by the drift chamber. As shown in the Figure 1.3, there is an island near $E / p=0.2$, which contains most of the electron candidates as well as some regions below 0.2 which will be argued to be negative pions misidentified as electrons.

Pions entering the calorimeter are typically minimum ionizing particles, loosing little of their incident energy in the calorimeter at a rate of 2 $\mathrm{MeV} \mathrm{g}{ }^{-1} \mathrm{~cm}^{2}$. Electrons, on the other hand, deposit a larger fraction of their momentum into the calorimeter. As a result, the energy deposited into the electromagnetic calorimeter is different for electrons and pions. Pions loose about 0.08 GeV of energy traversing the calorimeter independent their momentum thereby producing the constant signal in the calorimeter around 0.08 GeV . In order to reduce misidentified pions from the electron sample, the following cut
has been applied:

$$
\begin{equation*}
\mathrm{EC}_{\text {inner }}>0.08 \times p, \tag{1.1}
\end{equation*}
$$

where $p$ represents a particle's momentum and $\mathrm{EC}_{\text {inner }}$ the energy deposited into the inner part of the calorimeter.

Since the energy loss of pions is related to the calorimeter thickness, a correlation can be established between the energy deposited into the inner and outer layers of the calorimeter:

$$
\begin{equation*}
\frac{\mathrm{EC}_{\text {tot }}}{\mathrm{EC}_{\mathrm{inner}}}=\frac{13}{5} \tag{1.2}
\end{equation*}
$$

and results in the following cut for the energy deposition into the outer layer of the calorimeter:

$$
\begin{equation*}
\mathrm{EC}_{\mathrm{tot}}>0.2 \times p \tag{1.3}
\end{equation*}
$$

## Cherenkov Counter Cut

The Cherenkov counter has been used to further reduce the negatively charged pion background in the reconstructed electron sample. When the velocity of a charged particle is greater than the local phase velocity of light or when it enters a medium with different optical properties, the charged particle will emit photons. Cherenkov light is emitted at the critical angle $\theta_{c}$ representing the angle of Cherenkov radiation relative to the particle's direction. It can be

Fig. 1.3: $\mathrm{EC}_{\mathrm{inner}} / p$ versus $\mathrm{EC}_{\mathrm{tot}} / p$ before and after EC cuts $\left(\mathrm{EC}_{\mathrm{tot}}>0.2 p\right.$ and $\mathrm{EC}_{\text {inner }}>0.08 p$ ). After applying EC cuts about $46 \%$ of the events have been removed from the electron sample.
shown that the cosine of the Cherenkov radiation angle is inversely proportional to the velocity of the charged particle

$$
\begin{equation*}
\cos \theta_{c}=\frac{1}{n \beta}, \tag{1.4}
\end{equation*}
$$

where $\beta c$ is the particle's velocity and $n$ the index of refraction of the medium. The charged particle in time $t$ travels a distance $\beta c t$, while the electromagnetic waves travel $\frac{c}{n} t$. For a medium with given index of refraction $n$, there is a threshold velocity $\beta_{t h r}=\frac{1}{n}$, below which no radiation is emitted. This process may be used to distinguish between the highly relativistic electrons and the less relativistic pions based on the number of photons produced in the Cherenkov detector. The number of photons produced per unit path length of a particle with charge $Z e$ and per unit energy interval of the photons is proportional to the sine of the Cherenkov angle [2]

$$
\begin{gather*}
\frac{d^{2} N_{P E}}{d E d x}=\frac{\alpha z^{2}}{\hbar c} \sin ^{2} \theta_{c}=\frac{\alpha z^{2}}{\hbar c}\left[1-\frac{1}{\beta^{2} n^{2}(E)}\right]  \tag{1.5}\\
\frac{d^{2} N_{P E}}{d \lambda d x}=\frac{2 \pi \alpha z^{2}}{\lambda^{2}}\left[1-\frac{1}{\beta^{2} n^{2}(\lambda)}\right]  \tag{1.6}\\
\beta=\frac{v}{c}=\frac{p c}{\sqrt{(p c)^{2}+\left(m c^{2}\right)^{2}}} \tag{1.7}
\end{gather*}
$$

Taylor expanding Eq. 1.6 and keeping only the first two terms we get following

$$
\begin{equation*}
\frac{d^{2} N_{P E}}{d E d x}=\frac{\alpha z^{2}}{\hbar c} \sin ^{2} \theta_{c}=\frac{\alpha z^{2}}{\hbar c}\left[\beta^{2} n^{2}(E)-1\right] . \tag{1.8}
\end{equation*}
$$

The gas used in the CLAS Cerenkov counter is perfluorobutane, $\mathrm{C}_{4} \mathrm{~F}_{10}$, with index of refraction equal to 1.00153 . Approximately thirteen photoelectrons are produced by electrons traversing the Cherenkov detector. On the
other hand, calculations show that the number of photons produced by the negatively charged pions in the Cherenkov detector is approximately two. The theoretical results of the number of photons produced by the electrons and pions when passing through the Cherenkov counter are shown on Figure 1.4.

(b) For pions.

Fig. 1.4: Theoretical Calculation of the Number of Photoelectrons for electrons and pions.

The distribution of the number of photoelectrons measured in the Cherenkov detector and the energy deposition dependence on number of photoelectrons are shown on Figure 1.5 and Figure 1.6. Pions, misidentified as electrons appear on Figure 1.5 at nphe $<2.5$.

Fig. 1.5: The number of photoelectrons without cuts.

Fig. 1.6: The total energy deposited into the Calorimeter versus the Number of Photoelectrons.

## Geometric and Timing cuts

Negative pions may be misidentified as electrons when the electron scatters at a polar angle close to zero and is not observed by the detector. In order to reduce the electron sample contamination by those pions, geometrical cuts on the location of the particle at the entrance to the Cherenkov detector and time matching cuts have been developed by Osipenko [3]. For each CLAS Cherenkov detector segment the following cut has been applied

$$
\begin{equation*}
\left|\theta_{p}-\theta_{p}{ }^{\text {center }}-\theta_{p}{ }^{\text {offset }}\right|<3 \sigma_{p} \tag{1.9}
\end{equation*}
$$

where $\theta_{p}$ represents the measured polar angle with respect to a projectile plane for each electron event and $\sigma_{p}$ the width of the polar angle $\theta_{p}$. The Cherenkov counter's projective plane is an imaginary plane behind the Cherenkov detector where Cherenkov radiation would have arrived if it had moved the same distance from emission point to the PMT, without reflections in the mirror system. $\theta_{p}{ }^{\text {center }}$ is the polar angle from the CLAS detector center to the image of Cherenkov counter segment center and $\theta_{p}{ }^{\text {offset }}$ is the shift in the segment center position. In addition to geometrical cuts, timing cuts have been applied to match the time between a Cherenkov counter hit and the time of flight system.

The pion contamination in an electron sample was estimated by fitting the photoelectron distribution using two Gaussian distributions convoluted with a Landau distribution [4]:

$$
\begin{equation*}
N_{p e}=p_{0} e^{-0.5\left(\frac{x-p_{1}}{p_{2}}\right)^{2}}+p 4 \frac{1}{1-\left(\frac{x-p 5}{p 6}\right)}+p_{6} e^{-0.5\left(\frac{x-p_{7}}{p_{8}}\right)^{2}} . \tag{1.10}
\end{equation*}
$$

The fits in Figure 1.7.(a) suggest that the pion contamination in the electron sample is $9.63 \% \pm 0.01 \%$ before applying the OSI cuts and after the OSI cuts the contamination is about $4.029 \% \pm 0.003 \%$ (Figure 1.7.(b)).

Fig. 1.7: The number of photoelectrons before and after geometrical and time matching cuts.

### 1.2.2 Pion Identification

Charged pions are identified using a coincidence hit in the drift chamber and Time-of-Flight (ToF) counter. Pions are separated from the other charged particles by looking at the particle's momentum versus its velocity $(\beta)$. The particle velocity, $\beta=\frac{v}{c}$, is calculated from the difference of the RF time and the time-of-flight measurement in the ToF system with the path length from the
vertex to the ToF counters. The mass of the charged particle can be identified by combining the particle's $\beta$ with the particle's momentum obtained from the track measured by the drift chamber in the known magnetic field. The particle's mass in a magnetic field is given as

$$
\begin{gather*}
p=\frac{m \beta}{\sqrt{1-\beta^{2}}}  \tag{1.11}\\
m=p \sqrt{\left(\beta^{2}-1\right)}  \tag{1.12}\\
\beta=\frac{L_{\text {path }}}{t_{\text {flight }}}, \tag{1.13}
\end{gather*}
$$

where $m$ is the mass of the charged particle, $\beta$ its velocity, $p$ particle momentum, $L_{p a t h}$ the path length from the vertex to scintillators, and $t_{\text {flight }}$ the time of flight from the interaction vertex to the ToF system.

Using the above information (particle momentum from the drift chambers and the timing information from the ToF system), the mass squared of the charged particle was calculated and is shown on Figure 1.9. The pion mass band is distributed around zero. To isolate charged pions from the rest of the particles, a $3 \sigma$ cut on the momentum versus $\beta$ distribution has been applied [5].

In addition to the above $3 \sigma$ cut, fiducial volume cuts have been applied to improve charged pion identification. Since the drift chambers and scintillators are used for pion detection, the polar angle range where pions are detected is much larger than for electrons. For the EG1b experiment, pions were detected from $8^{\circ}$ to $180^{\circ}$ [5]. The pion identification code has been developed by Joshua

Fig. 1.8: The charged particle momentum versus $\beta$ distribution. The pion and proton bands are clearly separated.

Pierce [6].

### 1.3 Event Reconstruction Efficiency

The goal of this work is to measure the semi-inclusive asymmetry when an electron and a pion are detected in the final state. For this analysis, pions of opposite charge will be observed using the same scintillator paddles by flipping

Fig. 1.9: The charged particle momentum versus mass squared distribution for the $\vec{e} p \rightarrow \vec{e} \pi^{+} n$ electroproduction process. The bands around zero and one represent pions and protons respectively [5].
the CLAS torus magnetic field direction. Although pions will be detected by the same detector elements, electrons will intersect different detector elements. As a result, the electron reconstruction efficiency was evaluated in terms of the electron rate observed in two different scintillator paddles detecting the same electron kinematics.

### 1.3.1 Inclusive Electron Event Reconstruction Efficiency

The electron reconstruction efficiency for individual scintillator detectors using the 4.2 GeV EG1b data set is investigated below. Only the electron is detected in the final state (inclusive case). The pion contamination in the electron sample was removed by applying the cuts described above. The elec-
tron paddle numbers $10(\mathrm{~B}<0)$ and $5(\mathrm{~B}>0)$ were chosen respectively, because they contained the most electron events in a first pass semi-inclusive pion analysis of the data set. The electron kinematics (momentum, scattering angle and invariant mass) for these scintillators is shown on Figure 1.10.

Ratios of the inclusive electron rate, normalized using the gated Faraday cup and detected in scintillator paddles \# 5 and \# 10, were measured. The two ratios are constructed to quantify the CLAS detector's ability to reconstruct electrons in scintillator paddle \#5 using a positive Torus polarity and scintillator \#10 using the negative Torus polarity.

$$
\begin{align*}
& \frac{\mathrm{ND}_{3}, \mathrm{~B}>0, \text { Paddle Number }{ }^{e^{-}}=5}{\mathrm{ND}_{3}, \mathrm{~B}<0, \text { Paddle Number } \mathrm{e}^{-}=10}=1.57 \pm 0.16  \tag{1.14}\\
& \frac{\mathrm{NH}_{3}, \mathrm{~B}>0, \text { Paddle Number }{ }^{e^{-}}=5}{\mathrm{NH}_{3}, \mathrm{~B}<0, \text { Paddle Number }{ }^{e^{-}}=10}=1.76 \pm 0.17 \tag{1.15}
\end{align*}
$$

Notice the above ratios are statistically the same. The semi-inclusive analysis to be performed in this work will be taking ratios using an $\mathrm{ND}_{3}$ and $\mathrm{NH}_{3}$ target. Below is the observed ratio comparing the inclusive electrons observed in scintillator $\# 5$ for a positive torus polarity and an $\mathrm{ND}_{3}$ target to the electrons observed in scintillator $\# 10$ when the torus polarity is negative and the target is $\mathrm{NH}_{3}$.

$$
\begin{equation*}
\frac{\mathrm{ND}_{3}, \mathrm{~B}>0, \text { Paddle Number } e^{e^{-}}=5}{\mathrm{NH}_{3}, \mathrm{~B}<0, \text { Paddle Number }{ }^{e^{-}}=10}=1.55 \pm 0.15 \tag{1.16}
\end{equation*}
$$

The above ratios, which have been observed to be ammonia target independent, indicate a difference in an electron detector efficiency when the torus polarity is flipped. An electron detection efficiency "correction coefficient" is de-

(c)

Fig. 1.10: Electron Kinematics. (a) Electron Momentum(( $\left.\mathrm{NH}_{3}, \mathrm{~B}>0\right),\left(\mathrm{NH}_{3}\right.$, $\mathrm{B}<0),\left(\mathrm{ND}_{3}, \mathrm{~B}>0\right)$ and $\left.\left(\mathrm{ND}_{3}, \mathrm{~B}<0\right)\right)$, (b) Electron Scattering Angle $\theta\left(\left(\mathrm{NH}_{3}\right.\right.$, $\mathrm{B}>0),\left(\mathrm{NH}_{3}, \mathrm{~B}<0\right),\left(\mathrm{ND}_{3}, \mathrm{~B}>0\right)$ and $\left.\left(\mathrm{ND}_{3}, \mathrm{~B}<0\right)\right)$ and (c) W Invariant $\operatorname{mass}\left(\left(\mathrm{NH}_{3}, \mathrm{~B}>0\right),\left(\mathrm{NH}_{3}, \mathrm{~B}<0\right),\left(\mathrm{ND}_{3}, \mathrm{~B}>0\right)\right.$ and $\left.\left(\mathrm{ND}_{3}, \mathrm{~B}<0\right)\right)$
fined in terms of the above ratio and measured to be $\frac{\mathrm{ND}_{3}, \mathrm{~B}>0, \text { Paddle Number }{ }^{e^{-}}=5}{\mathrm{NH}_{3}, \mathrm{~B}<0, \text { Paddle Number }{ }^{e^{-}}=10}=$ 0.645 and $\frac{\mathrm{ND}_{3}, \mathrm{~B}<0, \text { Paddle Number }{ }^{\mathrm{e}^{-}}=10}{\mathrm{NH}_{3}, \mathrm{~B}>0, \text { Paddle Number }{ }^{e^{-}}=5}=1.82$. The impact of these corrections on the data is illustrated in the next section.

### 1.3.2 Exclusive and Semi-Inclusive Event <br> Reconstruction Efficiencies

The measured single pion electroproduction rate was compared to the MAID 2007 unitary model [7], that has been developed using the world data of pion photo and electro-production to determine the impact of using the above electron reconstruction efficiency "correction coefficient".

The MAID 2007 model has predictions of the total cross section for the following two cases that are relevant to our work:

$$
\begin{align*}
& \gamma^{*}+\operatorname{proton}\left(\mathrm{NH}_{3}\right) \rightarrow \pi^{+}+\text {neutron }  \tag{1.17}\\
& \gamma^{*}+\text { neutron }\left(\mathrm{ND}_{3}\right) \rightarrow \pi^{-}+\text {proton. } \tag{1.18}
\end{align*}
$$

The ratio of the pions detected in the scintillator paddles, located between the Cherenkov counter and electromagnetic calorimeter, is shown in Figure 1.11. Ratios were measured for four different cases. The intrinsic assumption is that, for the inbending case, positive pions and for the outbending case negative pions have the same trajectories with the same kinematics. In addition, negatively charged pions in the inbending field and positively charged pions in the outbending fields are detected by the same detector elements.

Using MAID 2007, the total cross section was calculated for the following invariant mass and four momentum transfer squared values: $1.7 \mathrm{GeV}<$ $\mathrm{W}<1.8 \mathrm{GeV}$ and $Q^{2}=1.1 \mathrm{GeV}^{2}[7]$.

## Pion Paddle Number vs Ratio of Counts

Fig. 1.11: Pion paddle number versus Ratio for Semi-Inclusive case.

$$
\begin{array}{r}
\sigma=\sigma_{T}+\epsilon \sigma_{L}+\sqrt{2 \epsilon(1+\epsilon)} \sigma_{L T} \cos \phi_{\pi}{ }^{C M}+\epsilon \sigma T T \cos 2 \phi_{\pi}^{C M}+  \tag{1.19}\\
+h \sqrt{2 \epsilon(1-\epsilon)} \sigma_{L T^{\prime}} \sin \phi_{\pi}^{C M}
\end{array}
$$

where $\phi_{\pi}{ }^{C M}$ is the pion azimuthal angle in the CM frame, $\epsilon=(1+2(1+$ $\left.\left.\frac{\nu^{2}}{Q^{2}}\right) \tan ^{2} \frac{\theta_{e}}{2}\right)^{-1}$ is the virtual photon polarization, $\nu=E_{i}-E_{f}$ the energy difference of the initial and final state electron, $Q^{2}=4 E_{i} E_{f} \sin ^{2} \frac{\theta_{e}}{2}$ the four momentum transfer squared, $\theta_{e}$ the electron scattering angle and $h$ the electron helicity. After applying corrections from the inclusive cases, the ratios were compared to the results from MAID2007. The difference of the measured and

MAID2007 model ratios for each pion paddle number is shown in Figure 1.12. One can argue using Figure 1.12 that the "inclusive corrections" do not impact single pion production rates for the exclusive cases.

Pion Paddle Number vs MAID2007 - Experiment(N(pi-,ND3) / N(pi+,NH3))
Before and After Inclusive Corrections

Fig. 1.12: Pion Paddle Number versus MAID2007 - Experiment ( $\mathrm{N}\left(\pi^{-}, \mathrm{ND}_{3}\right)$ $\left./ \mathrm{N}\left(\pi^{+}, \mathrm{NH}_{3}\right)\right)$. The Black and red data represent $\mathrm{B}>0 / \mathrm{B}<0$ and $\mathrm{B}<0 / \mathrm{B}>0$ cases respectively before corrections. The green and blue points represent the ratios for $\mathrm{B}>0 / \mathrm{B}<0$ and $\mathrm{B}<0 / \mathrm{B}>0$ after inclusive corrections.

### 1.4 Asymmetries

The double spin asymmetry measurements in this work are performed by comparing scattering events that occur when the incident probe spin and nuclear target spin are parallel to the scattering events that occur when the spins are anti-parallel.

### 1.4.1 Beam Charge Asymmetry

The helicity of the electron beam was flipped at a rate of 1 Hz . The helicity is prepared at the source such that helicity pairs are produced pseudo randomly.

Clock Sync Bit

Helicity Bit

Original/Complement state

Fig. 1.13: The Helicity State: A one bit signal from the beam injector gives the helicity information, whereas a sync bit with a 2 Hz frequency is generated at the same time and is equal to the helicity flip time.

If the first electron bunch is pseudo randomly chosen to be positive (negative) then it is labeled as the original helicity state and denoted in software by a 2 (1). The next helicity state is prepared to be a complement to the first state and labeled in the software as either a 4 , if the original helicity state was a 1 (negative), or 3 if the original helicity state was a 2 (positive). The helicity selection process is then repeated.

Figure 1.13 illustrates the signals used to label the helicity states. The
clock pulse (SYNC) is used to indicate that a change in the pockel cell used to define the helicity state may have occurred. The helicity bit identifies the helicity state that was set. The original/complement pulse identifies if the state is an original or complement helicity state. All three bits are recorded in the raw data file for each event and then converted to the labels 1, 2, 3, 4 during DST file production once the particles have been reconstructed.

Two scalers were used to record several ancillary detectors, such as a Faraday cup and several PMTs mounted on the beam line, according to their helicity label. One of the scalers was gated by the DAQ live time in order to record beam conditions when the DAQ was able to take data and not busy recording data. The second scaler remained ungated. Both scalers recorded the SYNC and Helicity signals from the injector along with the counts observed from ancillary detectors during the SYNC interval. The Faraday cup signal recorded by the gated helicity scaler is used to normalize the events reconstructed during the same helicity interval.

The beam charge asymmetry is defined in Eq. 1.20 and measured using the gated helicity scaler. For each run number, a gaussian fit was used to fit the beam charge asymmetry distributions as in Figure 1.14. The beam charge asymmetry is defined as

$$
\begin{equation*}
A_{\text {Beam Charge }}=\frac{\Sigma F C^{\text {hel1,hel } 2}-\Sigma F C^{\text {hel4,hel3 }}}{\Sigma F C^{\text {hel1,hel2 }}+\Sigma F C^{\text {hel4,hel3 }}} \tag{1.20}
\end{equation*}
$$

where $F C^{\text {hel1, hel2 }}\left(F C^{\text {hel4, hel3 }}\right)$ represents the Faraday cup counts observed for the original helicity 1 and 2 states (the complement helicity 3 and 4 states).

Fig. 1.14: Beam charge asymmetry for run $\# 28101$ using the gated Faraday cup counts for two helicity pairs (1-4 and 2-3 helicity pairs). $A_{1-4}=(11.5 \pm$ $4.4) \times 10^{-5}$ and $A_{2-3}=(-2.3 \pm 4.4) \times 10^{-5}$.

EG1b data sets, with the same half wave plane, target type, target polarization and beam torus, have been combined. The beam charge asymmetries have been calculated for the each run group and are listed in Table 1.2.

| Run Group | Half wave plane(HWP) | $A_{1-4} \times 10^{-4}$ | $A_{2-3} \times 10^{-4}$ |
| :---: | :---: | :---: | :---: |
| $28100-28105$ | +1 | $5.88 \pm 34.40$ | $4.03 \pm 34.36$ |
| $28106-28115$ | -1 | $7.53 \pm 22.30$ | $8.28 \pm 22.30$ |
| $28145-28240$ | +1 | $31.70 \pm 7.99$ | $30.40 \pm 7.99$ |
| $28242-28284$ | -1 | $49.6 \pm 10.8$ | $47.9 \pm 10.8$ |
| $28286-28324$ | +1 | $36.3 \pm 11.6$ | $37.0 \pm 11.5$ |
| $28325-28447$ | -1 | $21.1 \pm 13.4$ | $22.2 \pm 13.4$ |
| $28449-28479$ | +1 | $-11.6 \pm 16.5$ | $-21.6 \pm 16.5$ |

Table 1.2: Run Group versus Beam Charge Asymmetry.

### 1.4.2 Electron Asymmetry

A measurement of the electron cross section helicity difference needs to account for a possible helicity dependence of the incident electron flux (charge Asymmetry). Figure 1.15 shows the reconstructed electron rate asymmetry, before it is normalized by the gated Faraday Cup, as a function of the run number for the 4.2 GeV data set. The reconstructed electron asymmetry can be defined following way:

$$
\begin{equation*}
A_{N E S}^{+-}=\frac{\Sigma N E S^{+}-\Sigma N E S^{-}}{\Sigma N E S^{+}+\Sigma N E S^{-}} \equiv(2-3), \tag{1.21}
\end{equation*}
$$

or

$$
\begin{equation*}
A_{N E S}^{-+}=\frac{\Sigma N E S^{-}-\Sigma N E S^{+}}{\Sigma N E S^{-}+\Sigma N E S^{+}} \equiv(1-4) \tag{1.22}
\end{equation*}
$$

where $N E S^{+}\left(N E S^{-}\right)$represents number of electron scattered for the positive (negative) beam helicity.

Systematic effects on the asymmetry measurement may be investigated by separating the data into two groups based on which helicity state is set first. The first group (black data points) represents the electron asymmetry observed when the first (original) helicity state is negative and its complement state is positive (helicity state \#1 - state \#4). The second group (red data points) represents the asymmetry observed when the first state is positive and the complement state is negative (helicity state $\# 2-\# 3$ ). Both groups were divided into two subgroups based the target type used. The diamond points on the histogram represent the data for the $\mathrm{NH}_{3}$ target and the squares for the

Run Number vs NES Asymmetry

Fig. 1.15: Run Number versus Electron Asymmetry before FC normalization. The black and red points represent reconstructed electron asymmetry for the helicity 1-4 pair for $\mathrm{ND}_{3}$ and $\mathrm{NH}_{3}$ target respectively. The blue and green points represent the helicity pair $2-3$ for $\mathrm{ND}_{3}$ and $\mathrm{NH}_{3}$ respectively. The green line shows the sign of the half wave plane (HWP) and the purple line is the sign of the target polarization (TPol).
$\mathrm{ND}_{3}$ target. Two lines on the histogram are used to identify the sign of the half wave plate (HWP) and the target polarization (TPol). The relative spin orientation can be changed by either inserting a half wave plane (HWP) or by populating a different target polarization state with a different RF frequency. One would expect the asymmetry to change sign if either the HWP is inserted or the target polarization is rotated 180 degrees. As one can see for Figure 1.15 and Figure 1.16, the electron asymmetry changes sign if the HWP or Target Polarization is reversed.

(a) NH3, Tpol $>0$ and HWP $>0$.

(b) NH3, Tpol $<0$ and $H W P>0$.

Fig. 1.16: W versus ( $\left.N E S^{\text {hel42 }}-N E S^{\text {hel13 }}\right)$. The electron asymmetry changes sign when the HWP or Target Polarization is reversed.

The un-normalized reconstructed electron asymmetry has been calculated as:

$$
\begin{equation*}
A_{N E S}=\frac{\Sigma N E S^{\text {hel1,hel } 2}-\Sigma N E S^{\mathrm{hel} 4, \mathrm{hel} 3}}{\Sigma N E S^{\mathrm{hel} 1, \mathrm{hel} 2}+N E S^{\text {hel4,hel3 }}} \tag{1.23}
\end{equation*}
$$

and normalized by the Faraday cup

$$
\begin{equation*}
A_{\mathrm{NES}}^{\mathrm{FCnormalized}}=\frac{\frac{\Sigma N E S \text { hel1,hel2 }}{\Sigma F C \text { hel1,hel2 }}-\frac{\Sigma N E S \text { hel4,hel3 }}{\Sigma F C \text { hel4,hel3 }}}{\frac{\Sigma N E S \text { hel1,hel2 }}{\Sigma F C \text { hel1,hel2 }}+\frac{\Sigma N E S \text { hel4,hel3 }}{\Sigma F C \text { hel4,hel3 }}} \tag{1.24}
\end{equation*}
$$

Run Number vs NES Asymmetry

Fig. 1.17: Run number versus electron asymmetry after applying FC normalization. The black and red points represent the reconstructed electron asymmetry for the helicity 1-4 pair for $\mathrm{ND}_{3}$ and $\mathrm{NH}_{3}$ target respectively. The blue and green points are the helicity pair $2-3$ for $\mathrm{ND}_{3}$ and $\mathrm{NH}_{3}$ respectively. The green line shows the sign of the half wave plane (HWP) and the purple line is the sign of the target polarization (TPol).

### 1.4.3 Semi-Inclusive Asymmetries

The asymmetries from semi-inclusive pion electroproduction using proton or deuteron targets can be written in terms of the difference of the yield when the electron spin is parallel and antiparallel to the spin of the nucleon. There are four combinations of semi-inclusive asymmetries: $A_{\mathrm{NH}_{3}}^{\pi^{+}}, A_{\mathrm{NH}_{3}}^{\pi^{-}}$, $A_{\mathrm{ND}_{3}}^{\pi^{+}}$and $A_{\mathrm{ND}_{3}}^{\pi^{-}}$

$$
\begin{align*}
& A_{\mathrm{NH}_{3}}^{\pi^{+}}=\frac{\Sigma N_{\mathrm{NH}_{3, \pi^{+}} \uparrow}^{\uparrow}-\Sigma N_{\mathrm{NH}_{3, \pi^{+}}}^{\uparrow \downarrow}}{\Sigma N_{\mathrm{NH}_{3}, \pi^{+}}^{\uparrow \uparrow}+\Sigma N_{\mathrm{NH}_{3, \pi^{+}}^{\uparrow \downarrow}}}  \tag{1.25}\\
& A_{\mathrm{NH}_{3}}^{\pi-}=\frac{\Sigma N_{\mathrm{NH}_{3, \pi^{-}}^{\uparrow}}^{\uparrow}-\Sigma N_{\mathrm{NH}_{3, \pi^{-}}}^{\uparrow \downarrow}}{\Sigma N_{\mathrm{NH}_{3}, \pi^{-}}^{\uparrow}+\Sigma N_{\mathrm{NH}_{3, \pi^{-}}^{\uparrow \dagger}}}  \tag{1.26}\\
& A_{\mathrm{ND}_{3}}^{\pi^{+}}=\frac{\Sigma N_{\mathrm{ND}_{3, \pi^{+}} \uparrow}^{\uparrow}-\Sigma N_{\mathrm{ND}_{3, \pi^{+}}}^{\uparrow \downarrow}}{\Sigma N_{\mathrm{ND}_{3}, \pi^{+}}^{\uparrow \uparrow}+\Sigma N_{\mathrm{ND}_{3, \pi^{+}}^{\uparrow \dagger}}}  \tag{1.27}\\
& A_{\mathrm{ND}_{3}}^{\pi^{-}}=\frac{\Sigma N_{\mathrm{ND}_{3, \pi^{-}}}^{\uparrow \uparrow}-\Sigma N_{\mathrm{ND}_{3, \pi^{-}}}^{\uparrow \downarrow}}{\Sigma N_{\mathrm{ND}_{3}, \pi^{-}}^{\uparrow \uparrow}+\Sigma N_{\mathrm{ND}_{3, \pi^{-}}}^{\uparrow \downarrow}}, \tag{1.28}
\end{align*}
$$

where $N_{\mathrm{NH}_{3, \pi^{+}, \pi^{-}}^{\uparrow \downarrow}}\left(N_{\mathrm{NH}_{3}, \pi^{+}, \pi^{-}}^{\uparrow \uparrow}\right)$ and $N_{\mathrm{ND}_{3, \pi^{+}, \pi^{-}}^{\uparrow}}\left(N_{\mathrm{ND}_{3, \pi^{+}, \pi^{-}}^{\uparrow \uparrow}}\right)$ represent the number of $\pi^{+}$and $\pi^{-}$hadrons detected in the final state with the scattered electron when the spin of the initial electron beam was antiparallel (parallel) to the spin of the proton and neutron respectively.

The kinematic coverage for the events used in the measured asymmetries are shown on Figure 1.18 and Figure 1.19. The semi-inclusive asymmetries are listed in Table 1.3. The first group $A_{\text {hel1-hel4 }}$ represents the asymmetry measured when the first original electron spin (hel1) is antiparallel to the target nucleon spin and its complement state (hel4) is parallel, whereas the second
group $A_{\text {hel2-hel3 }}$ represents measuring the SIDIS asymmetry when the first helicity state is parallel (hel2) and its complement state is antiparallel to the spin of the nucleon. For the final measurement, the two groups are combined into one $A_{\text {hel42-hel13 }}$ set, in order to increase statistics. Instead of looking at original and complement electron helicity states, they have been combined into the positive (hel42) and negative (he13) helicity states, which are parallel and antiparallel to the spin of the target nucleon respectively.

Fig. 1.18: Invariant Mass versus $Q^{2}$.

The ratio of the combined semi-inclusive deep inelastic asymmetries ( $A^{\text {raw }}$ ) from Table 1.3, for two different torus settings have been corrected for the electron reconstruction efficiency. Figure 1.20 represents the raw asymmetry ratios before and after electron reconstruction efficiency corrections. The ratios have been calculated for each target and charged pion type. The SIDIS asymmetries before and after the correction are statistically the same. The result indicates that the electron reconstruction efficiency does not change the

asymmetries.

The data have been combined for each target type and asymmetries measured for two $x_{B}$ values (Table 1.4). The SIDIS asymmetries were calculated for the following kinematic range: electron scattering angle $17.5<\theta_{e}<18.5$, electron momentum $2.55 \mathrm{GeV}<\mathrm{P}_{e}<2.75 \mathrm{GeV}$, invariant mass $1.6 \mathrm{GeV}<\mathrm{W}<1.8 \mathrm{GeV}$, missing mass $\mathrm{M}_{x}>1.6 \mathrm{GeV}^{2}$ and momentum transfer squared $0.9 \mathrm{GeV}^{2}<\mathrm{Q}^{2}<1.3$ $\mathrm{GeV}^{2}$.

Fig. 1.20: The ratio of the SIDIS asymmetries for two torus field settings $\frac{A^{\mathrm{raw}}(\mathrm{B}>0)}{A^{\mathrm{raw}}(\mathrm{B}<0)}$ versus target and the charged pion type. The black squares represent the data before electron reconstruction efficiency and the red data - after electron reconstruction efficiency has been applied.

Table 1.5: $A_{\mathrm{NH}_{3}}^{\pi^{+}, \text {raw }}$ SIDIS Asymmetry.

### 1.4.4 Dilution Factor

To account for the contributions of polarized nucleons from the nitrogen nuclei in the ammonia target and the cooling material of the target (Helium) cell to the semi-inclusive rates, the measured raw double spin asymmetries have to be divided by a dilution factor. The dilution factor accounts for the fraction of events coming from the desired polarized target nucleon. The dilution factors are calculated by combining the data from runs using different target types. During the EG1b experiment, several runs were taken with Carbon ( $\mathrm{C}^{12}$ ) and an empty target cell (He). All the runs in this work used liquid Helium as the coolant during the experiment. The Carbon and empty target runs were used to estimate the dilution of the data by the background attributed to the interaction of the incident electron beam with the Nitrogen or Helium nucleons present in the target cell [8].

In order to calculate the dilution factor, we need to define the number of counts with beam helicity negative and positive for ammonia $\left(N_{\mathrm{A}}\right)$, Carbon $\left(N_{\mathrm{C}}\right)$ and empty target $\left(N_{\mathrm{MT}}\right)$ runs. All are weighted by the corresponding gated Faraday cup counts [9]. Normalized rates for Carbon and empty target types are defined as

$$
\begin{equation*}
{ }_{n} \mathrm{C}, \mathrm{MT}=\frac{N_{\mathrm{C}, \mathrm{MT}}^{+}+N_{\mathrm{C}, \mathrm{MT}}^{-}}{F C^{+}+F C^{-}} \tag{1.29}
\end{equation*}
$$

and

$$
\begin{equation*}
n_{\mathrm{A}}=\frac{1}{2}\left(\frac{N_{\mathrm{A}}^{+}}{F C^{+}}+\frac{N_{\mathrm{A}}^{-}}{F C^{-}}\right), \tag{1.30}
\end{equation*}
$$

where $n_{\mathrm{C}}$ is the rate from a Carbon target, $n_{\mathrm{MT}}$ is from an empty target and $n_{\mathrm{A}}$ is from one of the $\mathrm{NH}_{3}$ or $\mathrm{ND}_{3}$ ammonia targets.

The counts for all four targets (empty, Carbon and ammonia) can be expressed as the sum of counts from the entrance and exit window foils $\left(\rho_{\mathrm{F}}\right.$, $\left.l_{\mathrm{F}}, \sigma_{\mathrm{F}}\right)$, liquid Helium coolant $\left(\rho_{\mathrm{He}}, l_{\mathrm{He}}, \sigma_{\mathrm{He}}\right)$, $\operatorname{Carbon}\left(\rho_{\mathrm{C}}, l_{\mathrm{C}}, \sigma_{\mathrm{C}}\right)$, Nitrogen $\left(\rho_{\mathrm{N}}, l_{\mathrm{N}}, \sigma_{\mathrm{N}}\right)$, Hydrogen (Deuterium) $\left(\rho_{\mathrm{H}(\mathrm{D})}, l_{\mathrm{H}(\mathrm{D})}, \sigma_{\mathrm{H}(\mathrm{D})}\right)$.

$$
\begin{gather*}
n_{\mathrm{MT}}=\rho_{\mathrm{F}} l_{\mathrm{F}} \sigma_{\mathrm{F}}+\rho_{\mathrm{He}} L \sigma_{\mathrm{He}}=f \rho_{\mathrm{C}} l_{\mathrm{C}} \sigma_{\mathrm{C}}+\rho_{\mathrm{He}} L \sigma_{\mathrm{He}}  \tag{1.31}\\
n_{\mathrm{C}}=\rho_{\mathrm{F}} l_{\mathrm{F}} \sigma_{\mathrm{F}}+\rho_{\mathrm{C}} l_{\mathrm{C}} \sigma_{\mathrm{C}}+\rho_{\mathrm{He}}\left(L-l_{\mathrm{C}}\right) \sigma_{\mathrm{He}}, \tag{1.32}
\end{gather*}
$$

and

$$
\begin{equation*}
n_{\mathrm{A}}=\rho_{\mathrm{F}} l_{\mathrm{F}} \sigma_{\mathrm{F}}+\rho \operatorname{He}\left(L-l_{\mathrm{A}}\right) \sigma_{\mathrm{He}}+\rho_{\mathrm{A}} l_{\mathrm{A}}\left(\sigma_{\mathrm{N}}+3 \sigma_{\mathrm{H}(\mathrm{D})}\right), \tag{1.33}
\end{equation*}
$$

where $f \equiv \frac{{ }^{\rho} \mathrm{F}^{l} \mathrm{~F}^{\sigma} \mathrm{F}}{{ }^{\rho} \mathrm{C}^{l} \mathrm{C}^{\sigma} \mathrm{C}}, \sigma_{\mathrm{H}(\mathrm{D})}$ represents the Hydrogen (Deuteron) cross section. Using above system of equations, we define two new spectra to account for the Carbon target and the difference in the amount of Helium in ammonia targets vice versus the Carbon target. For a target cell with length L and
the Carbon target with length $l_{\mathrm{C}}$, the Carbon and LHe contributions can be written following way:

$$
\begin{equation*}
n_{12 \mathrm{C}}^{\prime}=\frac{L}{L+f l_{\mathrm{C}}} n_{\mathrm{C}}-\frac{L-l_{\mathrm{C}}}{L+f l_{\mathrm{C}}} n_{\mathrm{MT}}=\rho_{\mathrm{C}} l_{\mathrm{C}} \sigma_{\mathrm{C}} \tag{1.34}
\end{equation*}
$$

and

$$
\begin{equation*}
n_{4 \mathrm{He}}^{\prime}=\frac{(1+f) l_{\mathrm{He}}}{L+f l_{\mathrm{C}}} n_{\mathrm{MT}}-\frac{f l_{\mathrm{He}}}{L+f l_{\mathrm{C}}} n_{\mathrm{C}}=\rho_{\mathrm{He}} l_{\mathrm{He}} \sigma_{\mathrm{He}}, \tag{1.35}
\end{equation*}
$$

where $n_{12 \mathrm{C}}^{\prime}$ is the rate from the Carbon nucleus only and $n_{H e}^{\prime}$ is the rate from liquid Helium only. The length and densities are listed in Table 1.6.

We need to establish how the rate from the Carbon target is related to the rate from the $\mathrm{N}^{15}$ in $\mathrm{NH}_{3}$ and $\mathrm{ND}_{3}$. The cross section for $\mathrm{N}^{15}$ can be written in terms of the cross sections on $\mathrm{C}^{12}$ target material $\left(\sigma_{12 \mathrm{C}}\right)$ and on a bound neutron in $\mathrm{N}^{15}\left(\sigma_{\mathrm{n}}^{\prime}\right)$.

$$
\begin{equation*}
\sigma_{15 N} \approx \frac{7}{6} \sigma_{12 \mathrm{C}}+\sigma_{\mathrm{n}}^{\prime}=\left(\frac{7}{6}+\frac{\sigma_{\mathrm{n}}^{\prime}}{\sigma_{12 \mathrm{C}}}\right) \sigma_{12 \mathrm{C}} . \tag{1.36}
\end{equation*}
$$

It is assumed that when the scattering occurs on protons inside the target material, the ratio of $\frac{\sigma_{n}^{\prime}}{\sigma_{12 C}}=0$ and when the reaction happens on neutrons inside the target, the value of the ratio is $\frac{\sigma_{\mathrm{n}}^{\prime}}{\sigma_{12 \mathrm{C}}}=\frac{1}{6}$, because there are six bound neutrons in $\mathrm{C}^{12}$ [9].

Using the above quantities, the background represented by the number of counts due to the non-hydrogen and non-deuterium parts of the ammonia
target can be expressed as

$$
\begin{align*}
n_{\mathrm{B}} & =\left[\frac{\rho_{\mathrm{A}} l_{\mathrm{A}}}{\rho_{\mathrm{C}} \mathrm{l}_{\mathrm{C}}}\left(\frac{7}{6}+\frac{\sigma_{\mathrm{n}}^{\prime}}{\sigma_{12 \mathrm{C}}}\right)+f\right] n_{12 \mathrm{C}}^{\prime}+\left(L-l_{\mathrm{A}}\right) n_{4 \mathrm{He}}^{\prime} \\
& =n_{\mathrm{MT}}+l_{\mathrm{A}}\left[\frac{\rho_{\mathrm{A}}}{\rho_{\mathrm{C}}^{l} \mathrm{C}}\left(\frac{7}{6}+\frac{\sigma_{\mathrm{n}}^{\prime}}{\sigma_{12 \mathrm{C}}}\right) n_{12 \mathrm{C}}^{\prime}-n_{4 \mathrm{He}}^{\prime}\right] \tag{1.37}
\end{align*}
$$

The dilution factor $d_{\mathrm{f}}$ is

$$
\begin{equation*}
d_{\mathrm{f}}=\frac{n_{\mathrm{A}}-n_{\mathrm{B}}}{n_{\mathrm{A}}} . \tag{1.38}
\end{equation*}
$$

| Item | Description | Value |
| :---: | :--- | :--- |
| $\rho_{\mathrm{F}} \mathrm{F}_{\mathrm{F}}$ | Density times target length <br> for empty target. | Al: $167 \mu \mathrm{~m} ; 0.045 \mathrm{~g} / \mathrm{cm}^{2}$. Kapton: 384 <br> $\mu \mathrm{~m} ; 0.055 \mathrm{~g} / \mathrm{cm}^{2} . \quad$ Total=Al + Kap- <br> ton $=0.0996 \mathrm{~g} / \mathrm{cm}^{2}$ |
| $\rho_{\mathrm{C}} \mathrm{C}_{\mathrm{C}}$ | Density times target length <br> for Carbon target. | $0.498 \mathrm{~g} / \mathrm{cm}^{2}$ |
| f | The ratio of counts from <br> foils to the $\mathrm{C}^{12}$ slab in the <br> Carbon target. | 0.200 |
| $\rho_{\mathrm{He}}$ | He density. | $0.145 \mathrm{~g} / \mathrm{cm}^{3}$ |
| $L$ | The length of the target cell <br> from the entrance to exit <br> foil. | 1.90 cm |
| $\rho_{\mathrm{C}}$ | $\mathrm{C}^{12}$ density. | $2.17 \mathrm{~g} / \mathrm{cm}^{3}$ |
| $l_{\mathrm{C}}$ | Carbon target length. $^{0.23 \mathrm{~cm}}$ |  |
| $\rho_{\mathrm{NH}_{3}}$ | $\mathrm{NH}_{3}$ density | $0.917 \mathrm{~g} / \mathrm{cm}^{3}$ |
| $\rho_{\mathrm{ND}_{3}}$ | $\mathrm{ND}_{3}$ density | $1.056 \mathrm{~g} / \mathrm{cm}^{3}$ |
| $l_{\mathrm{A}}$ | Ammonia target length. $^{0.6 \mathrm{~cm}}$ |  |

Table 1.6: Length and density values for different types of target material reproduced from the EG1b experiment [9].

The dilution factor is compared below in Table 1.8:

| The fractional energy of the observed <br> final state hadron $(\mathrm{z})$ | Dilution Factor $\left(d_{\mathrm{f}}\right)$ |
| :--- | :---: |
| $\mathrm{NH}_{3}, \pi^{+} \& \& z=0.4$ | $0.160 \pm 0.02$ |
| $\mathrm{NH}_{3}, \pi^{+} \& \& z=0.7$ | $0.152 \pm 0.03$ |

Table 1.7: Calculated dilution Factor for $\mathrm{NH}_{3}$ target type.

| Reaction | Dilution Factor $\left(d_{\mathrm{f}}\right)$ |
| :--- | :---: |
| Resonance region | $0.11-0.13$ |
| Inclusive | $0.14-0.17$ |
| Semi-Inclusive | $0.122-0.182$ |

Table 1.8: Dilution Factor compared with other results [8] [10].

## Chapter 2

## Results

### 2.1 Semi-Inclusive Pion Asymmetries

The final results are presented in this chapter. They have been obtained by analyzing the data collected in 2000-2001 at Thomas Jefferson National Laboratory using a longitudinally polarized electron beam on a longitudinally polarized Hydrogen $\left({ }^{15} \mathrm{NH}_{3}\right)$ and Deuterium $\left({ }^{15} \mathrm{ND}_{3}\right)$ targets. The incident electron's energy was 4.2 GeV . The CEBAF Large Acceptance Spectrometer (CLAS) was used for particle detection. The measurements were made for the kinematic region where $x_{B} \geq 0.3$ and momentum transfer squared $\mathrm{Q}^{2}=1.1 \pm$ $0.2 \mathrm{GeV}^{2}$. The SIDIS asymmetries were measured at four different values of $x_{B}$ and are presented on Figure 2.1.

### 2.2 Systematic Errors

The results presented in the previous sections include only statistical uncertainties. However, the experimental setup and the cuts used for particle identification and background elimination are the sources of systematic errors. This section describes the methods used for estimating the systematic errors for each type of source. The systematic errors for the SIDIS asymmetries are shown

Fig. 2.1: $x_{B}$ versus SIDIS pion asymmetries.
in Table 2.1. The total systematic error is calculated by combining individual systematic errors in quadrature.

| Source | Systematic Error |
| :---: | :---: |
| Geometrical and timing cuts | $1.40 \times 10^{-2}$ |
| Electromagnetic calorimeter cut | $3.50 \times 10^{-2}$ |
| Dilution Factor | $1.87 \times 10^{-2}$ |
| Target and beam polarization | $0.64 \times 10^{-2}$ |
| Total | $4.26 \times 10^{-2}$ |

Table 2.1: Summery of the systematic errors for the $A_{\mathrm{NH}_{3}}^{\pi^{+}}$asymmetry.

### 2.2.1 Cut Dependence

The systematic errors associated with the electromagnetic cuts and fiducial cuts for electron identification were calculated by comparing the SIDIS asymmetries before and after cuts were applied. As can be seen, the effect due to the electromagnetic calorimeter and fiducial cuts is on the order of $3.5 \%$ and $1.4 \%$ respectively (Figure 2.2).

Fig. 2.2: $x_{B}$ versus $A_{\text {NH3 }}^{\pi^{+}}$SIDIS Asymmetry: (a) geometrical and timing cuts, (b) electromagnetic calorimeter cuts.

### 2.2.2 Dilution factor

Systematic effects related to the dilution factor were estimated following way: First, the SIDIS asymmetries were calculated for the standard values of the dilution factor. Then asymmetries were recalculated by changing the value of each parameter by the amount of its uncertainty. The difference between these two values is the systematic effect due to the dilution factor. The resulting shift is about $1.9 \%$ (Figure 2.3).

Fig. 2.3: $x_{B}$ versus $A_{\mathrm{NH} 3}^{\pi^{+}}$SIDIS Asymmetry.

### 2.2.3 Polarization

Systematic effects due to the target and beam polarization were estimated following way: First, the SIDIS asymmetries were calculated for the standard values of the $\mathrm{P}_{t} \times \mathrm{P}_{b}$ polarization. Then asymmetries were recalculated by changing the value of each parameter by the amount of its uncertainty. The difference between these two values is the systematic error associated with the target and beam polarization, which is approximately $0.6 \%$ (Figure 2.4).

Fig. 2.4: $x_{B}$ versus $A_{\mathrm{NH} 3}^{\pi^{+}}$SIDIS Asymmetry.

### 2.3 Semi-Inclusive Pion Asymmetries

The corrected measured semi-inclusive deep inelastic asymmetries $A_{\mathrm{NH} 3}^{\pi^{+}}$, $A_{\mathrm{NH} 3}^{\pi^{-}}, A_{\mathrm{ND} 3}^{\pi^{+}}$and $A_{\mathrm{ND} 3}^{\pi^{-}}$are shown below on Figure 2.5 and compared to the asymmetries measured by the HERMES experiment. The measured SIDIS asymmetries on the proton and deuterium targets are in good agreement within their combined uncertainties. The SIDIS asymmetries for longitudinally polarized Hydrogen $\left({ }^{15} \mathrm{NH}_{3}\right)$ and Deuterium $\left({ }^{15} \mathrm{ND}_{3}\right)$ targets are listed in Table 2.2 for four values of $x_{B}$. The asymmetries have been corrected for the target and beam polarization [11] and dilution factor from ref[12].

Fig. 2.5: $x_{B}$ versus SIDIS Asymmetry: (a) $A_{\mathrm{NH} 3}^{\pi^{+}}$, (b) $A_{\mathrm{NH} 3}^{\pi^{-}}$(c) $A_{\mathrm{ND} 3}^{\pi^{+}}$and (d) $A_{\mathrm{ND} 3}^{\pi^{-}}$. The solid black squares are measurements from ref[13] and the solid black diamonds represent SIDIS asymmetries measured using the data collected during the EG1b experiment. The error bar lines represent systematic uncertainty and the risers statistical uncertainty.

| $x_{B}$ | $A_{\mathrm{NH} 3}^{\pi^{+}} \pm$stat. $\pm$syst. | $A_{\mathrm{NH} 3}^{\pi^{-}} \pm$stat. $\pm$syst. |
| :---: | :---: | :---: |
| 0.30 | $0.1644 \pm 0.0504 \pm 0.0191$ | $0.1378 \pm 0.0745 \pm 0.0183$ |
| 0.35 | $0.2733 \pm 0.0400 \pm 0.0229$ | $0.1183 \pm 0.0583 \pm 0.0176$ |
| 0.40 | $0.3308 \pm 0.0499 \pm 0.0407$ | $-0.0917 \pm 0.0753 \pm 0.0361$ |
| 0.45 | $0.2521 \pm 0.1257 \pm 0.0387$ | $-0.1908 \pm 0.1942 \pm 0.0374$ |
| $x_{B}$ | $A_{\mathrm{ND} 3}^{\pi^{+}} \pm$stat. $\pm$syst. | $A_{\mathrm{ND} 3}^{\pi^{-}} \pm$stat. $\pm$syst. |
| 0.30 | $0.2273 \pm 0.0317 \pm 0.0351$ | $0.1286 \pm 0.0320 \pm 0.0240$ |
| 0.35 | $0.0209 \pm 0.0314 \pm 0.0164$ | $0.1904 \pm 0.0319 \pm 0.0306$ |
| 0.40 | $0.3368 \pm 0.0322 \pm 0.0583$ | $0.1080 \pm 0.0330 \pm 0.0386$ |
| 0.45 | $0.2408 \pm 0.0377 \pm 0.0485$ | $0.5125 \pm 0.0392 \pm 0.0787$ |

Table 2.2: Semi-inclusive asymmetries on the proton and deuterium targets $\left(A_{\mathrm{NH} 3}^{\pi^{+}, \pi^{-}}\right.$and $\left.A_{\mathrm{ND} 3}^{\pi^{+}, \pi^{-}}\right)$.
